

# **Chapter 3: The Reinforcement Learning Problem** **(Markov Decision Processes, or MDPs)**

Objectives of this chapter:

- ❑ present Markov decision processes—an idealized form of the AI problem for which we have precise theoretical results
- ❑ introduce key components of the mathematics: value functions and Bellman equations

# The Agent-Environment Interface

Agent and environment interact at discrete time steps:  $t = 0, 1, 2, 3, \dots$

Agent observes state at step  $t$ :  $S_t \in \mathcal{S}$

produces action at step  $t$ :  $A_t \in \mathcal{A}(S_t)$

gets resulting reward:  $R_{t+1} \in \mathcal{R} \subset \mathbb{R}$

and resulting next state:  $S_{t+1} \in \mathcal{S}^+$

# Markov Decision Processes

---

- ❑ If a reinforcement learning task has the Markov Property, it is basically a **Markov Decision Process (MDP)**.
- ❑ If state and action sets are finite, it is a **finite MDP**.
- ❑ To define a finite MDP, you need to give:
  - **state and action sets**
  - one-step “dynamics”

$$p(s', r | s, a) = \Pr\{S_{t+1} = s', R_{t+1} = r \mid S_t = s, A_t = a\}$$

- there is also:

$$p(s' | s, a) \doteq \Pr\{S_{t+1} = s' \mid S_t = s, A_t = a\} = \sum_{r \in \mathcal{R}} p(s', r | s, a)$$

$$r(s, a) \doteq \mathbb{E}[R_{t+1} \mid S_t = s, A_t = a] = \sum_{r \in \mathcal{R}} r \sum_{s' \in \mathcal{S}} p(s', r | s, a)$$

# The Agent Learns a Policy

---

**Policy** at step  $t$  =  $\pi_t$  =

a mapping from states to action probabilities

$\pi_t(a | s)$  = probability that  $A_t = a$  when  $S_t = s$

Special case - *deterministic policies*:

$\pi_t(s)$  = the action taken with prob=1 when  $S_t = s$

- ❑ Reinforcement learning methods specify how the agent changes its policy as a result of experience.
- ❑ Roughly, the agent's goal is to get as much reward as it can over the long run.

---

# The Meaning of Life

(goals, rewards, and returns)

# Return

---

Suppose the sequence of rewards after step  $t$  is:

$$R_{t+1}, R_{t+2}, R_{t+3}, \dots$$

What do we want to maximize?

At least three cases, but in all of them,  
we seek to maximize the **expected return**,  $E\{G_t\}$ , on each step  $t$ .

- Total reward,  $G_t$  = sum of all future reward in the episode
- Discounted reward,  $G_t$  = sum of all future *discounted* reward
- Average reward,  $G_t$  = average reward per time step

# Episodic Tasks

---

**Episodic tasks:** interaction breaks naturally into episodes, e.g., plays of a game, trips through a maze

In episodic tasks, we almost always use simple *total reward*:

$$G_t = R_{t+1} + R_{t+2} + \dots + R_T,$$

where  $T$  is a final time step at which a **terminal state** is reached, ending an episode.

# Continuing Tasks

---

**Continuing tasks:** interaction does not have natural episodes, but just goes on and on...

For continuing tasks we would use *discounted return*:

$$G_t = R_{t+1} + \gamma R_{t+2} + \gamma^2 R_{t+3} + \dots = \sum_{k=0}^{\infty} \gamma^k R_{t+k+1},$$

where  $\gamma, 0 \leq \gamma \leq 1$ , is the **discount rate**.

shortsighted  $0 \leftarrow \gamma \rightarrow 1$  farsighted

Typically,  $\gamma = 0.9$

# An Example: Pole Balancing

---

Avoid **failure**: the pole falling beyond a critical angle or the cart hitting end of track

As an **episodic task** where episode ends upon failure:

reward = +1 for each step before failure

$\Rightarrow$  return = number of steps before failure

As a **continuing task** with discounted return:

reward = -1 upon failure; 0 otherwise

$\Rightarrow$  return =  $-\gamma^k$ , for  $k$  steps before failure

In either case, return is maximized by avoiding failure for as long as possible.

# Another Example: Mountain Car

---

Get to the top of the hill  
as quickly as possible.

reward = -1 for each step where **not** at top of hill

⇒ return = - number of steps before reaching top of hill

Return is maximized by minimizing  
number of steps to reach the top of the hill.

# A Trick to Unify Notation for Returns

- ❑ In episodic tasks, we number the time steps of each episode starting from zero.
- ❑ We usually do not have to distinguish between episodes, so instead of writing  $S_{t,j}$  for states in episode  $j$ , we write just  $S_t$
- ❑ Think of each episode as ending in an absorbing state that always produces reward of zero:

- ❑ We can cover all cases by writing  $G_t = \sum_{k=0}^{\infty} \gamma^k R_{t+k+1}$ ,

where  $\gamma$  can be 1 only if a zero reward absorbing state is always reached.

# Rewards and returns

- The objective in RL is to maximize long-term future reward
- That is, to choose  $A_t$  so as to maximize  $R_{t+1}, R_{t+2}, R_{t+3}, \dots$
- But what exactly should be maximized?
- The discounted return at time  $t$ :

$$G_t = R_{t+1} + \gamma R_{t+2} + \gamma^2 R_{t+3} + \gamma^3 R_{t+4} + \dots \quad \begin{array}{l} \text{the discount rate} \\ \gamma \in [0, 1) \end{array}$$

$\gamma$	Reward sequence	Return
0.5(or any)	1 0 0 0...	1
0.5	0 0 2 0 0 0...	0.5
0.9	0 0 2 0 0 0...	1.62
0.5	-1 2 6 3 2 0 0 0...	2

$$G_t = R_{t+1} + \gamma R_{t+2} + \gamma^2 R_{t+3} + \gamma^3 R_{t+4} + \cdots \quad \gamma \in [0, 1)$$

- Suppose  $\gamma = 0.5$  and the reward sequence is

$$R_1 = 1, R_2 = 6, R_3 = -12, R_4 = 16, \text{ then zeros for } R_5 \text{ and later}$$

- What are the following returns?

$$G_4 = 0 \quad G_3 = 16 \quad G_2 = -4 \quad G_1 = 4 \quad G_0 = 3$$

- Suppose  $\gamma = 0.5$  and the reward sequence is all 1s.

$$G = \frac{1}{1 - \gamma} = 2$$
